2 ABSTRACT

3 Mobile phone addiction has been increasingly linked to poorer academic outcomes among
4 undergraduates, but the mechanisms underlying this association remain unclear. Drawing on
5 social cognitive theory, this study examined whether academic procrastination mediates the
6 relationship between mobile phone addiction and academic performance and whether campus
7 relational contexts shape these pathways among computer science students at a Chinese
8 undergraduate university. A total of 353 students were recruited through random sampling,
9 and 334 valid responses were retained. Survey data on mobile phone addiction and academic
10 procrastination were combined with objective academic records. Multiple regression and bootstrap
11 analyses showed that mobile phone addiction negatively predicted academic performance
12 ($B = -0.446$, $p < 0.001$) and positively predicted academic procrastination ($B = 0.462$,
13 $p < 0.001$). Academic procrastination negatively predicted academic performance ($B = -0.258$,
14 $p < 0.001$) and partially mediated the association between mobile phone addiction and academic
15 performance, accounting for 26.70% of the total effect. Additional analyses showed that dormitory-
16 level mobile phone addiction and academic procrastination tendencies were positively associated
17 with the corresponding individual behaviors, whereas a more favorable mentor-group learning
18 environment weakened the adverse associations along the core pathways. Among four academic
19 risk prediction models, XGBoost achieved the best overall balance (accuracy = 0.836, F1 = 0.745).
20 The evidence points to academic procrastination as one pathway linking mobile phone addiction
21 to poorer academic performance and highlights the relevance of campus peer and mentor-group
22 contexts for higher-education risk screening and intervention.

Abstract

Methane plume segmentation in satellite imagery is constrained by the preservation of weak foreground evidence during hierarchical feature propagation. Under sparse plume occupancy, weak signal contrast, unstable plume morphology, background-dominant scenes, and heterogeneous sensor conditions, convolutional aggregation, normalization, spatial compression, and global dependency modeling can reduce plume-background separability before spatial recovery. This study formalizes this representation bottleneck as hierarchical representational dissolution and proposes encoding-path representational regeneration as the corresponding design principle for weak-foreground methane plume segmentation. Based on this principle, we develop MSSM-UNet, which combines a multi-scale sparse-selective encoder, residual gate modulation, auxiliary gate supervision, and a gate-guided Mamba bottleneck to preserve weak plume evidence while supporting long-range dependency modeling and plume-body recovery. The framework is evaluated on the EMIT benchmark and on curated Sentinel-2 and GF-5 settings for heterogeneous-sensor validation. On EMIT, MSSM-UNet achieves 79.65% MIoU and 71.09% Foreground Recall. It improves over CNN/UNet baselines by 0.62–1.40 percentage points in MIoU and 4.28–4.88 points in Foreground Recall, over Transformer baselines by 5.19–6.31 and 9.52–14.94 points, and over Mamba baselines by 4.66–5.21 and 1.57–7.01 points. Cross-sensor evaluation reaches 76.37% MIoU and 84.71% F1 on Sentinel-2, and 88.05% MIoU and 93.26% F1 on GF-5. Dissolution analysis, causal ablation, feature-evolution evidence, and SHAP-based attribution consistently show that regeneration-oriented representation learning improves foreground retention, concentrates decision evidence on methane-relevant cues, and strengthens subsequent plume delineation. These findings establish a representation-centered mechanism for methane plume segmentation and define a broader design direction for remote-sensing weak-foreground segmentation.

Keywords: methane plume segmentation, satellite remote sensing, weak-foreground segmentation, representation learning, Mamba, heterogeneous-sensor robustness

面向环境监测的多源遥感甲烷羽流轻量化 M²-UNet 分割方法¹

作者：许乾剑·孙神健·邹刚

河北农业大学

摘·要：针对多源遥感影像中甲烷羽流目标小、边界模糊、形态不规则和背景干扰强等问题，本文提出一种轻量化·M²-UNet·分割方法。该方法以·U-Net·为基础，在编码端引入多尺度卷积分支，在瓶颈层嵌入轻量化·Mamba·全局建模模块，并通过跳跃连接特征融合增强边缘恢复能力。基于·EMIT、哨兵 2 号和高分 5 号影像数据集开展实验。结果表明，在·EMIT·测试集上，模型的·Precision、Recall、F1-Score·和·IoU·分别达到 81.03%、68.62%、86.65% 和 79.29%，参数量仅为 4.66M。与·SDSC-UNet、UNetMamba、STARCOP·和·SegFormer·相比，所提方法在分割精度与轻量化之间取得了更优平衡。
